Chapter 1

The Problem and Its Setting

The issue of adolescent motherhood creates complex problems because it affects both the mothers and their children and the entire community. This study aims to assess how teenage mothers manage their challenges while they raise their children and rely on their support networks. The research will investigate how adolescent mothers receive parental guidance and what support systems exist for them and their academic and vocational aspirations. Unintended motherhood is a major problem in the Philippines, and approximately one out of every ten births is done by teens (UNFPA, 2020). Adolescent mothers face multiple challenges, which include social stigma and social poverty, and their limited ability to access educational and medical services. Previous research has shown that teenage mothers face mental health problems, which include depression and anxiety, but they can develop parenting abilities. Teen mothers have higher depression rates, and they lack social support and self-esteem when compared to adult mothers, according to Besenek 2021. Hodgkinson 2014 identified the mental health challenges that teenage parents experience, which create obstacles that prevent them from getting assistance. The social isolation and maternal competence and weight/shape concerns of teenage mothers predicted their postpartum

depression according to Birkeland 2005. The research by Lesser 1999 showed that teenage mothers face multiple health issues, which include difficulties in parenting, and they experience unfavorable conditions during childbirth. The research findings demonstrate that teen mothers need specialized intervention programs, which will help them develop both their mental health and parenting abilities.

The lived experiences of adolescent mothers in San Agustin, Surigao del Sur, Caraga Region present an informational work which examines the daily activities of mothers who serve as in-service staff members throughout their work period while they fulfill their duties of caring for others and progressing through various stages of their emotional and psychological, and social development. The research investigates how teenage mothers experience parenthood through their emotional state and mental health and ability to care for their children. The research was conducted to assess their ability to fulfill their responsibilities as parents and to establish their support network. The study could identify community support elements and government programs and social welfare development agencies, and non-governmental organizations.

Adolescent motherhood continues to be a significant social and public health matter because young mothers mostly face negative health results and difficulties with their social and emotional health. Adolescent mothers use their personal life experiences as evidence to demonstrate which factors affect their health and parenting abilities, and this knowledge will help develop better support methods. Luttges et al. (2021) examine how teenage mothers and young mothers who experience their first pregnancy and subsequent pregnancies make decisions and achieve different results. Huda et al. (2021) investigated adolescent motherhood in developing countries by studying how

different educational and economic factors produce distinct sociodemographic outcomes. The[1] study by Kumar and Huang (2021) investigates how teenage motherhood affects maternal health and child development throughout their research on the impact of economic difficulties which[6] lead to unfavorable results for both children and mothers in Kenyan informal settlements. The[1] research studies demonstrate that adolescent motherhood develops from multiple factors which[7] create a need to tackle social issues that create this condition in order to improve young mothers and their families well-being.[7,8] The study has two main restrictions which[9] include[10] its small sample size and its selection of adolescent mothers who use specific governmental[10] services. The[1] research is based[11] on self-reported data which[12] introduces potential bias. The[1] study provides vital information about[13] adolescent mothers who reside[13] in San Agustin, Surigao del Sur, which can be employed to create[13] policies and interventions that will[13] enhance the welfare of adolescent mothers and their children.

Review of Literature and Studies

Adolescent pregnancy is a global issue that has been widely researched and examined in many countries, including the Philippines. The[1] literature review organizes and combines research studies which[15] investigate[14] the actual experiences of adolescent mothers to demonstrate their challenges and need for complete[15] support and program assistance.

Challenges Faced by Adolescent Mothers in the Philippines

The Philippines experiences various difficulties which harm[16] the physical health and mental well-being[8] and[16] social development of its young mothers who become mothers during their teenage years. The[1] Philippines experiences its own special challenges which[17] make life difficult for adolescent mothers

because it has one of the highest teenage pregnancy rates in Southeast Asia. Young[1] mothers face difficulties during their parenting journey because they experience three main challenges, which include their inability to obtain medical services and their need for social assistance and[18] the societal prejudice against teenage motherhood (Gatbonton, 2021). Adolescent[1] mothers face multiple challenges because their communities evaluate them according to traditional gender expectations, which create pressure to follow established social norms.

The educational experience of adolescent mothers in the Philippines stands as[19] their most important[19] problem. Childcare[1] responsibilities lead many young mothers to leave school which[20] creates[21] challenges for them in finishing[21] their studies. Their[1] educational break leads to permanent economic effects which result[22,23] in restricted work options and decreased earning capabilities according[22] to Gatbonton 2021. The[1] educational system in the Philippines creates major obstacles for adolescent mothers because people believe education functions as the primary method to escape poverty. Young[1] mothers who pursue vocational courses and online education programs face challenges because these educational options remain unavailable and too costly for many according[24,25] to Coast et al. 2021[25] [25].

Adolescent mothers need emotional support because it represents a major public health issue. Research[1] shows that young mothers often experience feelings of isolation guilt[26] and[26] anxiety because they struggle to balance motherhood with their other responsibilities (Kotoh et al., 2022). Teenage[1] mothers experience additional emotional pain because they face societal stigma which[27] results in their peers judging them. Adolescent[1] mothers show higher rates of depression which[28] leads to mental health problems that increase their risk of developing depression (Lena et al., 2021). Adolescent[1] mothers who

experience emotional difficulties might face negative outcomes because they lack the necessary coping skills to handle their situation.

Adolescent mothers experience difficulties because they do not have enough healthcare services. Young[1] mothers in the Philippines face difficulties in obtaining appropriate prenatal and postnatal healthcare because of their financial limitations and the healthcare facilities that are too far away and[29] because they do not know about the available medical services (Boateng et al., 2023). Inadequate[1] healthcare delivery systems lead to pregnancy and childbirth complications which[30] increase the risk of maternal and infant death during these processes. The[1] young mothers do not obtain[32] the essential resources which help[31] them[32] guide their children toward healthy growth. The[1] insufficient[34] maternal health programs which exist[33,34] for adolescent mothers do not succeed in meeting[34] the complete requirements[34] and special needs[34] of this age group according[33] to research conducted[34] by Naidoo, Muthukrishna, and Nkabinde (2019).

Adolescent mothers experience family dynamics issues because their lives undergo sudden transformations. In[1] the Philippines, young mothers encounter difficulties because their families fail to provide sufficient support, which results in feelings of abandonment and stress. Young[1] mothers face family rejection when their relatives consider their pregnancy to be shameful or caused by their irresponsible behavior (Gill 2021).[35] Young[1] mothers face challenges in child care because their support system breaks down, which leads to negative effects on their mental health and emotional state. The[1] financial demands of child-rearing without proper assistance[37] become too much to handle, which forces[37] parents to depend[37] on informal caregiving solutions[37] and community assistance[37] programs (Olorunsaiye et al. 2022).[36]

The Philippines faces social challenges that extend beyond its borders because of teenage pregnancy. The[1] community regards adolescent motherhood as socially unacceptable because the family honor and reputation system dominates local cultural values. Adolescent[1] mothers face community exclusion because their peers and teachers and[38] relatives judge them and treat them unfairly. Adolescent[1] mothers experience difficulties reintegrating into society after they give birth because people perceive them as violating established gender expectations (Coast et al. 2021).[39] The[1] process of social exclusion creates effects that produce mental health problems which[40] prevent adolescent mothers from building social networks that would assist them in handling their new responsibilities.

Adolescent mothers use different coping methods, but most of them depend on informal support networks which[41] include their friends and family members. Young[1] mothers rely on these informal networks to receive[43] both emotional support and financial assistance which[42] helps[43] them deal with[43] their parenting responsibilities (Kotoh et al., 2022). The[1] support systems which exist[44] for adolescent mothers prove to be unreliable because some mothers must handle their problems without assistance. Through[1] their experiences[45] adolescent mothers develop resilience[46] because[47] they learn to handle all[47] demands of motherhood while they[47] discover effective methods to tackle their encountered[45] difficulties.[45] The[1] absence of essential resources together[48] with support systems[48] makes it difficult for people to manage their problems because they experience continuous emotional distress which[48] leads to financial difficulties.

The role of education and vocational training in supporting adolescent mothers exists as an essential method to reduce the negative impacts which result[49] from early pregnancy.Young[50] mothers who require educational support can pursue their studies through alternative programs which meet[51] their specific

requirements. Educational programs designed for adolescent mothers provide flexible scheduling options along with childcare services and counseling support to help students complete their studies and achieve better future outcomes (Naidoo et al., 2019). The implementation of educational programs and skills training for adolescent mothers enables their escape from poverty cycles while decreasing early pregnancy consequences for themselves and their children.

Adolescent mothers in the Philippines need complete programs which deliver educational resources and medical services and psychological assistance. The programs need to address the specific requirements which adolescent mothers face through their physical and mental and social development needs. The public needs to stop treating teenage pregnancy as a shameful experience to create a society which accepts and supports young mothers. The process of enhancing resource access and support systems will enable adolescent mothers to overcome their existing challenges and create better prospects for themselves and their children according to Cox et al. 2021 .

Global Perspective on Adolescent Parenting

Adolescent parenting stands as a worldwide problem that impacts millions of young people throughout different regions which present their own distinct challenges. Adolescent mothers in Nepal encounter major obstacles because their society lacks necessary resources and holds negative views toward them. The research conducted by Acharya and Sharma (2021) studied how mothers in Chitwan District, Nepal experienced life while raising autistic children because they faced healthcare access challenges and social discrimination which hindered their ability to care for their offspring. The study demonstrates that rural areas need dedicated support systems which help adolescent mothers who live in these regions with limited resources. The findings indicate that

interventions need to address both mental health needs and community-based support requirements.

In Western countries, adolescent parenting is often shaped[62] by cultural expectations and a lack of comprehensive emotional support. Kazal[1] et al. (2021) conducted a study among minority adolescent mothers in the United States, focusing on their birth stories, support networks, and emotional health. The[1] researchers found that emotional support during the perinatal period proved[64] essential for the[64] young mothers to achieve their complete wellbeing.[8,63,64] Adolescent[1] mothers who received emotional and practical support from family, friends, and community resources exhibited better mental health outcomes and were more equipped to manage the challenges of early motherhood.

Adolescent mothers in Ghana experience multiple challenges which particularly[65] affect their ability to provide childcare. Twintoh[1] et al. (2021) employed ecological systems theory to examine how teenage mothers in Ghana practiced childcare. The[1] research discovered that adolescent mothers performed their duties because of societal pressures and family relationships and[66] their inability to obtain resources. The[1] mothers depended[67] on informal networks because they did not have[67] access to formal childcare education. The[1] situation requires complete[69] programs which[69] will teach adolescent mothers practical childcare abilities[69] and provide them psychological[68] assistance.[69]

The lived experiences of mothers parenting children with serious health conditions create an additional influence on adolescent mothers who live in different parts of the world. Al[1] Omari et al. (2021) studied how mothers who bring up their children with leukemia experience mental and emotional problems that come with their responsibilities. The[1] research showed that adolescent mothers who take care of their seriously ill children face extra difficulties because of their caregiving responsibilities which[70] lead to their

development of depression and anxiety and their experience of social withdrawal. The research findings demonstrate that adolescent mothers who manage chronic health conditions need special support services which will help them and their children and protect their psychological well-being.

In South Africa, adolescent mothers also face the challenge of decision-making and agency in the context of early motherhood. The study conducted by Pillay (2021) studied young mothers from Johannesburg who reported that early motherhood restricted their future possibilities. The adolescent mothers faced difficulties because they needed to handle both their educational goals and their responsibilities as mothers. The study by Pillay shows that educational institutions need to provide young mothers with more flexible learning options and support systems which allow them to continue their studies while they parent their children.

Adolescents and young adults with autistic siblings face emotional and developmental challenges which differ from those experienced by their peers. Iannuzzi et al. (2022) conducted a study examining the lived experiences of adolescents and young adults with siblings diagnosed with ASD. The young individuals in the study assumed caregiving responsibilities which resulted in emotional distress. The same phenomenon can occur to adolescent mothers who encounter identical challenges of handling their obligations. The study results require development of specific mental health programs together with peer support networks which will assist adolescents in handling their caregiving duties while safeguarding their mental health.

Chronic illnesses also significantly affect adolescents in motherhood. Holmström and Söderberg (2021) studied the experiences of young people living with type 1 diabetes, focusing on the challenges they face while managing their condition. The study found that coping with such chronic

conditions often led to feelings of isolation and reduced quality of life. Adolescent[1] mothers who also deal with chronic health conditions, such as diabetes, face compounded challenges in parenting. This[1,81] underscores the importance of providing specialized healthcare and psychological support to adolescent mothers who suffer from chronic illnesses.

The role of social support during pregnancy is another critical aspect that influences adolescent motherhood. Mabetha[1] et al. (2022) investigated young women's experiences of support networks during pregnancy in Soweto, South Africa. The[1] study revealed that young mothers who had strong support networks, whether from family, friends, or healthcare providers, felt more empowered and experienced fewer mental health issues. The[1] findings highlight the importance of building robust support systems for adolescent mothers, as these networks significantly impact their mental and emotional well-being.[8]

Research on the experiences of transgender and gender-diverse youth provides insight into the broader context of adolescence and parenting. Tyni[1] et al. (2024) conducted a systematic review and qualitative synthesis of the lived experiences of transgender and gender-diverse youth. While[1] not related to adolescent mothers, the study offers valuable insights into how marginalized youth navigate their identities and cope with societal pressures. It[1] highlights the importance of inclusive support systems that address the unique challenges faced by adolescent mothers who may also identify as gender-diverse.

Mental health challenges faced by adolescent mothers are evident in informal settlements in Nairobi, Kenya. Wainaina[1] et al. (2021) investigated the psychosocial[82] challenges of pregnant and postpartum adolescents in these areas. Their[1] study found that these young mothers often faced mental stress due to poverty, limited access to healthcare, and societal stigma. However,[1] they

also developed individual coping strategies, such as building strong community ties and relying on peer support. The research calls for the implementation of mental health services tailored to the specific needs of adolescent mothers, particularly in underserved regions.

Factors Contributing to Adolescent Pregnancy

Adolescent pregnancy remains a significant global concern, influenced by various socio-cultural, economic, and psychological factors. One critical determinant is the family environment, where adolescents raised in dysfunctional families with histories of substance abuse may be more susceptible to early pregnancies. Studies show that adolescents who grow up in environments marked by substance abuse are at a higher risk of engaging in risky sexual behaviors (Meulewaeter et al., 2022). Such behaviors often stem from a lack of parental guidance, supervision, and emotional support, which are essential for the development of healthy relationships and responsible decision-making. The experience of growing up amidst alcohol and drug abuse can lead to the normalization of risky behaviors, increasing the likelihood of early motherhood (Meulewaeter et al., 2022).

Socioeconomic factors, including poverty and lack of access to education, also contribute significantly to adolescent pregnancy. Young women in impoverished areas are often deprived of opportunities for higher education, which can lead to early sexual activity and unintended pregnancies. In Ghana, for example, teenage mothers face multiple challenges in balancing their responsibilities as young mothers and the desire for educational advancement. Research shows that the effects of teenage motherhood significantly hinder educational attainment, thereby perpetuating cycles of poverty and limiting future career opportunities (Morgan et al., 2022). The stigma surrounding teenage mothers

further exacerbates their social isolation, making it difficult for them to seek support and guidance.

Moreover, social isolation and lack of access to digital resources also impact adolescent pregnancy. A study on Roma teenage mothers during the COVID-19 lockdown highlighted the compounded difficulties of being socially isolated and digitally excluded. These young mothers struggled with limited access to prenatal care, education, and social support, all of which increased their vulnerability to early pregnancy (Velicu et al., 2022). Digital exclusion prevented these mothers from accessing critical information about contraception and sexual health, which are necessary for preventing unintended pregnancies. The lack of connection to broader societal support networks further exacerbates their circumstances.

Psychological factors, such as trauma and mental health issues, also play a significant role in adolescent pregnancy. For some, the experience of being stigmatized or marginalized leads to a sense of otherness, which can result in a lack of self-worth and poor decision-making regarding sexual health. Individuals with chronic conditions, such as inflammatory bowel disease, have reported heightened levels of stigma and discrimination, which can exacerbate their mental health struggles and increase vulnerability to risky behaviors (Muse et al., 2021). Such experiences of stigma and marginalization often intersect with early pregnancy, as these adolescents may turn to early sexual relationships as a way to cope with their emotional pain.

Access to healthcare and sexual education is another critical factor influencing adolescent pregnancy. Studies conducted in Uganda among teenage first-time mothers reveal that many young mothers perceive a lack of adequate healthcare during the immediate and early postpartum periods. These young women expressed a need for more targeted healthcare services that address

their specific needs as adolescents (Namutebi et al., 2022). The absence of comprehensive sexual education in schools further exacerbates this issue, as many adolescents lack the knowledge needed to prevent pregnancy and protect their health.

The presence or absence of supportive networks also has a profound impact on adolescent pregnancy outcomes. In some cases, young mothers benefit from strong social support networks that provide emotional and practical assistance, enabling them to navigate the challenges of motherhood. However, others experience feelings of isolation and rejection, which can exacerbate their struggles. For example, the lived experiences of adolescents living with HIV in Ghana underscore the importance of a dedicated support system, as these young people face unique challenges in managing their health while also navigating the emotional and physical demands of motherhood (Doat et al., 2020). The lack of support can make it harder for adolescent mothers to cope with the stresses of motherhood, increasing the likelihood of poor outcomes.

Educational interventions aimed at reducing adolescent pregnancy must address both the immediate and long-term factors contributing to this issue. The experiences of Thai adolescent mothers, for example, emphasize the challenges of breastfeeding and infant care, which can be hidden and unaddressed due to societal pressures and lack of support (Nuampa et al., 2020). Providing education on child-rearing and maternal health can empower adolescent mothers to make informed decisions, improve their health outcomes, and reduce the likelihood of further pregnancies during adolescence.

The stigmatization of adolescent mothers can hinder their ability to access support and resources. The stigma faced by Hispanic sexual minority youth, for example, can prevent them from seeking help from their families or

communities (Lozano et al., 2021). In many cases, adolescent mothers face similar stigma, which can lead to social exclusion, mental health issues, and difficulties in parenting. Reducing the stigma associated with adolescent pregnancy through education and awareness campaigns can help mitigate these negative outcomes and provide young mothers with the resources they need to succeed.

Hopes for a Brighter Future

Adolescent pregnancy is one of the burning social problems, particularly in developing nations, when the social, socioeconomic, and educational factors contribute to the worsening of the situation with the young mothers. The personal experience of adolescent mothers tends to point at the severe difficulties these persons struggle with trying to reconcile the need to care about their child and the urge to study and realize their own ambitions. The young mothers in most instances are isolated and marginalized and least supported by their families and communities. Shieu et al. (2021) examined the lived experiences of younger nursing home residents and found out that their unmet needs and struggles may resonate with the experience of young mothers, which explains the necessity of putting vulnerable populations into complete support. All these experiences imply that adequate care, education, and emotional support play a vital role in enhancing the quality of life of the adolescent mothers, who tend to be isolated and not easily accessible.

The case in most African nations is no better, as expectant and parenting teenagers tend to experience special issues in the areas of education and healthcare access. A review by Ajayi et al. (2023) has examined the lived experience of pregnant and parenting adolescents all over Africa and discovered that these youths are unable to balance their maternal duties and attempt to complete their education. The social stigma that comes with the

teen[93] pregnancy in most African societies also complicates the situation to an extent[93] that the young mothers have been pushed[94] on[93] the periphery of the society.[93] This[1,95] makes it very difficult to meet their long-term educational and professional objectives since they are caught[96] in a poverty and lack of opportunity cycle.

In addition, adolescent pregnancy does not limit itself to a particular region but can impact heavily[97] on the mental health of a young mother over an extended period of time. Besenek[1] and Gurlek (2021) have investigated the psychosocial[82] differences between adolescent and adult mothers and found out[98] that adolescent mothers are characterized[99] by greater stress, anxiety, and depression. These[1] emotional strains tend to be worsened by the[101] social pressure imposed on them,[100] and[101] the inability to cope with the roles of mothering and self-care. This[1] emotional strain further makes it hard to handle the day in day out[102,1] parenting and may greatly impede their personal and academic development.

Another way in which early pregnancies affect educational[104] experiences of adolescent mothers is that their pregnancies force them to leave school. Gatbonton[1] (2021) studied the experiences of teen mothers in the Philippines who were trying to further their college studies. The[1] analysis has found out[105] that teen mothers have significant challenges that include lack[105] of childcare, lack[105] of income, and social stigma and[105] all these challenges make it hard to resume their studies. Through[1] these struggles, quite a number[107] of the mothers said that the most thing they wanted[106] was to complete their education and offer their children a better life. This[1,108] underlines[109] the necessity[109] to change the[109] learning systems and provide young mothers with more opportunities to learn.

The effects of adolescent pregnancy on educational opportunities are not only constrained to formal education statement[110] but also the manner in which young mothers look at their future possibilities. A[1] case study carried out[111] by Gatsinzi

(2022) on out-of-school teenage mothers in Rwanda identified that several young mothers were disillusioned and hopeless regarding their education opportunities. Nevertheless, the research also found that given a chance to go back to school via a system designed to suit their requirements, most adolescent moms were much better in their educational results as well as social interactions. This highlights the need to offer special educational assistance to young mothers because that would give them an opportunity to experience personal development and social mobility.

Monterona (2020) conducted an investigation on the recurring pregnancies among the adolescent mothers in the Philippines and discovered that most young mothers struggle with a cycle of early pregnancies, which only impedes their efforts of being out of the poverty hole. Such recurring pregnancies are caused by lack of proper sexual education and accessibility of contraceptives. The research has shown that young mothers who lack the benefit of the exposure to sexual education or family planning services are usually caught in the poverty trap as they cannot get to work or have the chance of pursuing education due to child care requirements. This case demonstrates why there is a necessity to implement extensive sexual education courses that will enable the young ladies to make sound judgments concerning their reproductive health.

Pueyo (2022) emphasized the position and obstacles of teenage mothers in the Philippines and the overall meaning of the provision of support services. The research discovered that adolescent mothers are commonly exposed to overwhelming odds in the aspect of poverty, lack of access to health facilities and absence of supportive family set up. These difficulties are complicated by the fact that social and emotional support is also vital to the mental health of the adolescent mothers. Pueyo also made it clear that these young mothers

should receive specially adapted support services that not only ensure a proper level of their immediate health but also give them emotional, social, and educational resources needed to overcome the poverty cycle and get a higher quality of life.

Emotional and mental well-being of a teenage mother is the essential part of their well-being. Sharma and Golhar (2022) talked about parent-adolescent relationship where they argued that emotional and psychological interactions between adolescent mothers and their families were crucial. The article has noted that most teen mothers feel not supported by their parents; a factor that contributes to loneliness and distress. The family members should have good communication and emotional support which plays a crucial role in assisting the adolescent mothers to overcome various complexities in their lives, among them being the emotional burden of having a child at a very tender age.

As was highlighted by the United Nations Population Fund (UNFPA, 2020), it is important to end teenage pregnancy in the Philippines, where the rates of teenage pregnancies are still high. The policy brief presented the necessity of the more elaborate sexual education programs, better access to healthcare, and more helpful support systems of young mothers. The investigation conducted by the UNFPA about teenage pregnancy in developing nations shows that almost a third of all women in these regions give birth to their children at an early age, which once again highlights the importance of the need to target teenage pregnancy on a global level (UNFPA, 2022). To establish a better future of young women, the primary causes of teenage pregnancy including the absence of education, poverty, and insufficient healthcare need to be addressed.

Supporting Adolescent Mothers: Interventions, Challenges, and Recent Findings

Adolescent motherhood is a major social health challenge particularly in the low and middle income nations whereby the rate of teenage pregnancy is still high. Adolescent mothers have several problems, such as low educational backgrounds, poverty, and psychological problems. A number of studies have attempted to learn about the experiences of teen mothers and the efficacy of interventions meant to help them. Such interventions are usually done on the basis of education, mental health support, and maternal and child health outcomes.

Luttges et al. (2021) discussed the views of teenage mothers and young mothers with regard to repeat pregnancies and found out which factors can lead to the probability of having another pregnancy in adolescence. The researchers established that social and economic issues, and the lack of family planning facilities, were associated with increased levels of repeat pregnancy in teenage mothers. By dealing with these underlying factors with specific interventions, one would be able to decrease the number of adolescent pregnancies, as well as to elevate outcomes of both mothers and their children. Time trends and sociodemographic disparities among adolescent mothers of 74 countries were studied in a study by Huda et al. (2021). The research revealed that socioeconomic status is an important factor that increases the likelihood of teenagers getting pregnant with poor adolescents having more chances of getting pregnant. Another significant aspect of the research was the need to make education and family planning services more accessible as a part of an extensive approach toward decreasing the number of adolescent pregnancies and helping young mothers.

The article by Kumar and Huang (2021) was focused on analyzing the effects of adolescent motherhood in Kenya, especially in informal settlements on maternal health, parenting, and child development. Their results showed that

the adolescent[147] motherhood in low-income and high-adversity settings is more prone to postpartum depression, maternal health and[147] child development. This[1] paper indicates that mental health support interventions, parenting education, and healthcare access are critical towards enhancing the well-being[8] of teenage mothers and their offspring.

Sangsawang et al. (2021) performed a randomized controlled trial to evaluate the efficacy of psychosocial[82] intervention of midwives and family members to prevent postpartum depression in first-time adolescent mothers. The[1] researchers concluded that psychosocial[82] support interventions had a significant effect in reducing the rate of postpartum depression and enhancing maternal mental health. These[1] results demonstrate the significance of mental health interventions as a significant element of assistance to adolescent mothers.

Bhowmik et al. (2021) resolved the question of child marriage and teenage motherhood in Bangladesh, pointing to the fact that young women are vulnerable in such situations. The[1] paper highlights that legal and social actions are necessary to stop child marriages and assist teen mothers. Education,[1] financial assistance and[148] family planning services play an important role in dealing with the causes of teen pregnancies and changing the destiny of these young mothers.

Haque et al. (2022) examined the relationship between stunting during adolescent[149] mothers and stunting in childhood in Bangladesh. This[1] research established that the children born of stunted adolescent mothers were more susceptible to being stunted themselves[150] thus indicating intergenerational consequences of bad nutrition. Interventions[1] which involve[151] both enhancing[152] maternal nutrition and ensuring[152] that mothers receive appropriate healthcare

services are essential in[152] ending this cycle and enhancing[152] the health outcomes of the[152] mothers and children.

The authors Mohammad et al. (2021) examined the impact of social support, parenting stress, and maternal self-efficacy on postpartum depression in adolescent mothers in Jordan. In[1] their paper, they determined that the more social support was[153] received by adolescent mothers,[153,154] the less they experienced postpartum depression. The[1] results indicate that social support, and that of family, peers, and healthcare workers[155] is a key component in improving the mental health of the mother and decreasing the occurrence of postpartum depression.

Hans et al. (2022) studied[156] the importance of the childbirth support provided to[15] African American adolescent mothers by their[156] fathers, grandmothers, nurses, doctors, and doulas. The[1] authors concluded that multisource-based care enhanced[157] maternal outcomes, such as less[157] stress and postpartum recovery. This[1,158] points out[160] the need to engage different stakeholders when attending to adolescent mothers so that[160] they can get[160] emotional[159] and practical support they require.

Diabelkova et al. (2023) observed the outcome of teen pregnancies and the risk factors, with the influence of teen pregnancies on maternal and neonatal health. The[1] researchers discovered that the adolescent[161] mothers are more likely to experience negative consequences of pregnancy, such as preterm birth and low birth weight. The[1] study highlights the importance of early interventions (prenatal care and education) to enhance the[162] pregnancy outcomes of[162] adolescent mothers.

The article by Powers et al. (2021) presented the[164] guidance[163] on how adolescent parents and children should be taken care of.[164] Their[1] clinical report indicated the need of[165,166] pediatricians and other health practitioners to support the[166] adolescent[16]

mothers, especially with regard to meeting the special needs of the young parents and their children. The report recommends a comprehensive intervention that encompasses mental health treatment, education, and family participation in enhancing the outcome of the adolescent mothers and their children.

Theoretical Lens

The theoretical construct of this research raises a number of existing theories that offer useful information about the experiences and issues of teen mothers. These theories include the Ecological Systems Theory by Bronfenbrenner, the Theory of Psychosocial Development by Erikson, the Social Learning Theory, and Resilience Theory and these theories present a holistic approach to the problems of adolescent motherhood. The theories have a different way of bringing out a different facet towards the experiences, challenges and strengths of the adolescent mothers that can be considered to have been unraveled.

The Ecological Systems Theory by Bronfenbrenner provides a strong platform of examining the environmental forces that influence development of adolescent mothers. Bronfenbrenner (1979) argues that human development takes place in a sequence of linked systems that surround and are enclosed by other systems that have an impact. Microsystem which involves the local environment such as school and family is also essential in learning about how the adolescent mothers interact and support each other on a day-to-day basis. As an example, family relations contribute to their motherhood experience. The mesosystem which entails the relation among various microsystems including family, school, and community also serves to bring out the way adolescent mothers maneuver through these systems. In this regard, the ability to access supportive educational programs or community services may affect their ability to carry

out their mother roles and at the same time have personal ambitions. The exosystem and macrosystem give further insights and the policies of the government, the access to healthcare and the social norms shape the way the adolescent mothers would live with motherhood. With this ecological prism, a subtle perspective on how individual, family, community, and societal factors interact with the well-being of adolescent mothers is possible.

The Theory of Psychosocial Development developed by Erikson gives significant psychological information about the predicament that adolescent mothers have to go through. According to Erikson (1968), the stage of identity versus role confusion is usually associated with adolescents who are facing difficulty in developing a sense of self. This developmental task can become difficult to teenage mothers in transition to motherhood. The demands of parenting and identity formation are mostly conflicting which brings a psychological tension as these young women struggle to balance their new sense of self with the need to be responsible mothers. This step is critical in the process of realizing how the adolescent mothers feel of their identity, self esteem, and capabilities as parents. Adolescent mothers have been found to be often confused by their roles and feel psychologically distressed, especially when their parenting role is seen to disrupt their personal growth (Bates et al., 2014). The theory by Erikson, thus, is useful in examining the internal conflicts facing adolescent mothers when they are dealing with the dynamics of identifying themselves and at the same time learn to become a caregiver.

The Social Learning Theory is a theory created by Bandura (1977) which highlights the importance of observation and imitation when learning new behaviors. This theory is specifically applicable in learning how adolescent mothers develop parenting practices and behavior. Teen mothers do tend to base their parenting methods on the models that they see in their families,

peer groupings and the wider patterns of society. An example is when an adolescent mother was brought up in an environment where care giving was typified by neglect or corporal punishments, she might end up emulating the same behavior with her children. Instead, healthy parenting behaviors can be modeled using positive role models who could be supportive family members or other mentors. Through the application of the Social Learning Theory, we can understand the role played by the social environments of the adolescent mothers in their knowledge about motherhood. Their parenting skills and social networks reinforcement not only determine their self-efficacy in coping with the demands of motherhood, but also shape them (Schunk, 2012). This theory provides a guideline of the effect of external factors such as family and societal networks on the shaping of parenting practices among adolescent mothers. Resilience Theory supplements the existing theories by taking into consideration the property of the adaptive capacities of adolescent mothers to adversity. Luthar, Cicchetti and Becker (2000) state that resilience is the capacity to prosper even when there are risk factoring forces, like trauma, poverty or discrimination. Adolescent mothers are usually burdened by various issues among them being financial pressure, inaccessibility to education and social stigmatization. Nevertheless, most of young mothers show their resilience through the utilization of protective factors like personal strengths, social support and community resources. These aspects help them to work through and accommodate the motherhood difficulties. The resilience perspective assists in bringing out strong and flexible characteristics of the adolescent mothers indicating how they can endure tough situations. Studies have shown that in cases where the adolescent mothers are able to receive support systems be it in form of family, peer or community based programs, the mothers stand a better chance of overcoming the impediments as well as

developing a feeling of control in their parenting roles (Masten, 2001). This theory offers a critical perspective that explains the way in which teenage mothers not only manage their challenges but also succeed and improve on the experience.

The combination of these four theoretical perspectives offers an integrated concept of what adolescent mothers go through. The theory of ecological systems by Bronfenbrenner focuses on how various environmental layers impact their development, and Erikson theory of psychosocial development provides the insight into the psychological problems they are struggling with. Social Learning Theory explains the role of observation and modeling in acquiring parenting behaviors by teen mothers andResilience Theory highlights the adaptive mechanisms that enable them to deal with adversity. Collectively, these theories provide a multidimensional perspective to the determinants of the experiences, challenges, and strengths of adolescent mothers. This theoretical approach will inform the research into how adolescent mothers can negotiate their roles and identities and environments in complex ways.

This study aims at giving an in-depth idea of the lived experiences of adolescent mothers by using the Ecological Systems Theory, Psychosocial Development Theory by Erikson, theory of Social Learning, and theory of Resilience. The theories allow a multi-layered perspective of examining the ecological, psychological, behavioral, and resilience-related aspects that affect the experiences of adolescent mothers. The investigation of these frameworks within the framework of adolescent motherhood will help to incorporate valuable knowledge into the role and identity of the young mothers, who go through all the complexities of their roles and identities. These observations can be used to design policies and interventions that will assist adolescent

mothers to have the resources, support, and opportunities to emerge as individuals and parents.

Research Flow

The research flow for the study follows a structured process, starting with the preparation phase, where the research design was finalized by confirming objectives and reviewing relevant literature. Ethical approvals were sought from the Research Ethics Committee of the USPF, the institution's ethics board, and data collection instruments, such as interview guides for Focus Group Discussions (FGD), In-depth Interviews (IDI), and Key Informant Interviews (KII), were prepared. The participant selection phase involved defining inclusion criteria, recruitment of participants through coordination with the MSWDO and MHO, and selecting 12 adolescent mothers using purposive sampling, ensuring a mix of single and living-in mothers.

Figure 1. Research Flow

In the data collection phase, various methods are employed to capture the experiences of adolescent mothers. FGD sessions were held with 12 participants from San Agustin, Surigao del Sur, focusing on general experiences and challenges. IDIs were conducted with a smaller group of 6 mothers, providing in-depth insights into individual experiences. Additionally, 3 KIIs with parents of adolescent mothers gather perspectives on family dynamics and the impact of adolescent motherhood. The data from all interviews were recorded, transcribed, and analyzed using thematic analysis, following a phenomenological approach to uncover key themes. Triangulation was used to

compare data from various sources to gain a deeper understanding of the experiences.

The reporting phase consisted of interpreting the findings and drafting the research report. The[1] findings were summarized[233] and linked to the research questions and objectives, with[234] the report being[234] revised to ensure[234] scholarly standards. The[1] research was then presented[235] to stakeholders, such as MSWDO and MHO of San Agustin, Surigao del Sur, and other relevant agencies. Finally,[1] conclusions and recommendations were made,[236] suggesting[236] potential interventions, policy improvements, and further research areas[236] to support adolescent mothers effectively.

Statement of the Problem

The study aimed to examine the lived experiences of adolescent mothers in San Agustin, Surigao del Sur. Specifically,[1] it focused on the following: the child-rearing practices and the ways they provided for the emotional and physical needs of their children; identifying and analyzing the support systems available to adolescent mothers, both from family and the community; and exploring the hopes and aspirations of the young mothers, including their educational goals and life plans.

Significance of the Study

The findings of this study are significant for stakeholders who are directly involved in providing support and interventions for adolescent mothers.

Helping Professions. Social[1] workers, counselors, psychologists, and other professionals can use the study's findings to better understand[237] the experiences, challenges, and coping mechanisms of adolescent mothers. This[1] understanding can guide the development of more effective psycho-social[82] interventions and support services.

Schools and Educational Stakeholders. Teachers, school administrators, and education program developers can utilize the insights to design programs and policies that support adolescent mothers in continuing their education or returning to school, as well as to inform comprehensive sex education programs.

Social Workers and Non-Government Organizations (NGOs). NGOs and social service organizations can tailor their programs and interventions to address the specific needs and challenges faced by adolescent mothers, ensuring that support services are relevant and effective.

Government Agencies. Agencies responsible for social welfare, health, and education can use the study to inform policy development and resource allocation for programs targeting adolescent mothers and their families.

Community Members and Leaders. Local community leaders and organizations can identify areas where support is needed and work to create a more nurturing and supportive environment for adolescent mothers.

Future Researchers. The study provides baseline data and insights that future researchers can build upon to further explore adolescent motherhood, parenting challenges, and support interventions.

Research Participants. Participants may benefit from the study by gaining a platform to share their experiences and challenges as adolescent mothers. Indirect benefits may include raising awareness of their needs within the community and informing them about the development of support programs and activities. The study may also contribute to the improvement of services for adolescent mothers in San Agustin, Surigao del Sur.

Definition of Terms

The following are defined conceptually and operationally.

Adolescence.[241] is a developmental stage in human life that marks the transition from childhood to adulthood, typically between the ages of 13 and 19 years, characterized by physical, psychological, and social changes (Steinberg, 2005).

Adolescent mothers. are[1,242] young women aged between 13 and 19 years who give birth to children during their teenage years, often facing challenges related to health, education, and socioeconomic status (UNICEF, 2019).

In this study, adolescent mothers are females aged 13 to 19 years who have given birth at least once and are either single or living with a partner at the time of data collection.

Living-in partners. are[1] individuals who are cohabiting and sharing a household without the legal status of marriage (United Nations Population Fund, 2012).

In this study, living-in partners refer to participants' partners who are[243] cohabiting with them, but[243] are not married at the time of data collection.

The Municipal Health Office (MHO). is[1,244] a local government agency responsible for managing healthcare services and promoting public health within a municipality (Republic of the Philippines Department of Health, 2007).

The MHO in San Agustin, Surigao del Sur, is responsible for providing maternal and child health services to adolescent mothers in the area.

The Municipal Social Welfare and Development Office (MSWDO). is[1,245] a local government agency responsible for providing social welfare services to vulnerable populations, including support for adolescent mothers (Philippines Department of Social Welfare and Development, 2015).

The MSWDO in San Agustin, Surigao del Sur, provides social services such as[246] counseling, financial assistance, and family support to adolescent mothers.

Social support. refers[1] to the assistance or comfort provided by family, friends, or community resources to help individuals cope with stress and challenges (Cohen & Wills, 1985).

In this study, social support refers to the emotional, informational, and instrumental support received by adolescent mothers from their families, partners, and local services.

Single mothers. are[1] women who are raising children independently, without cohabiting with a partner or spouse (Bronfenbrenner, 2005).

In this study, single mothers refer to adolescent mothers who are not living with a partner or spouse and are raising their children alone.

Teenage pregnancy. is[1] defined as a pregnancy occurring in females under the age of 20, often associated with higher risks for both the mother and child (World Health Organization, 2013).

Teenage pregnancy in this study refers to the condition of being pregnant during adolescence (ages 13-19) and is specifically studied[247] among adolescent mothers in San Agustin, Surigao del Sur.

Chapter 2

Research Methodology

The section contains the details of conducting a qualitative study on the "Lived Experiences of Adolescent Mothers" involving a carefully structured research methodology to capture the richness and depth of their experiences.

Research Design

This study adopts a phenomenological approach, specifically utilizing Colaizzi's method, which is widely used in qualitative research to explore and understand the lived experiences of participants (Colaizzi, 1978). Colaizzi's method involves several stages, beginning with the collection of detailed descriptions of the phenomena under investigation. These descriptions are then analyzed by extracting significant statements, formulating meanings, and organizing them into themes. This approach aims to provide a deep understanding of how adolescent mothers in San Agustin, Surigao del Sur, perceive their experiences and challenges, particularly in terms of their coping capacities, support systems, and parenting roles. The phenomenological method is well-suited for this study, as it focuses on exploring participants' subjective experiences and the meanings they attach to those experiences (Creswell, 2013).

In line with the recommendations for enhancing the validity of qualitative research, this study also incorporates member checking as a key component of the research process. Member checking involved sharing the findings with the participants to ensure that the interpretations accurately reflect their lived experiences. This process will provide an opportunity for participants to clarify, confirm, or challenge the researcher's interpretations, thereby enhancing the credibility and trustworthiness of the findings (Lincoln & Guba, 1985). By combining Colaizzi's phenomenological method with member checking, this study aims to offer a comprehensive and validated understanding of the complex realities faced by adolescent mothers in San Agustin, Surigao del Sur.

Research Participants

The research participants for this study are adolescent mothers residing in San Agustin, Surigao del Sur, who received services from the Municipal Social Welfare and Development Office (MSWDO) and the Municipal Health Office (MHO). A purposive sampling method was used to select participants based on specific criteria, ensuring that a diverse representation of experiences is captured. The total number of participants is 12, consisting of 6 solo mothers and 6 mothers living with partners. The study used three different data gathering methods: 12 participants for Focus Group Discussions (FGD), 6 participants for In-Depth Interviews (IDI) (composed of 3 single mothers and 3 mothers living with partners), and 3 Key Informant Interviews (KII), focusing on 2 parents and 1 local health/social worker.

Exclusion Criteria

To ensure the scientific merit and safety of the study, specific exclusion criteria were applied. Participants who do not meet the inclusion criteria, such as those under the age of 13 or over the age of 19 at the time of data gathering, were excluded from the study. Additionally, adolescent mothers who have not been mothers for at least six months were excluded, as this criterion ensures that participants have had sufficient time to reflect upon and articulate their experiences of motherhood, parenting challenges, and available support systems. The aim is to include individuals who have had a reasonable period of engagement with the responsibilities of motherhood, thus providing a richer and more comprehensive understanding of their lived experiences.

Withdrawal Criteria

Participants may withdraw from the study at any time without penalty or consequence. Circumstances under which a participant might be withdrawn include but are not limited to: (1) the participant expressing discomfort with the interview questions or data collection process, (2) the participant experiencing

emotional or psychological distress due to the subject matter discussed, (3) a change in the participant's circumstances that prevents them from continuing the study (e.g., relocation, health issues), or (4) if the participant explicitly requests to withdraw their participation. If a participant chooses to withdraw, their data will be excluded from the study unless they consent to the continued use of their data up to the point of withdrawal. All participants will be reminded of their right to withdraw at any stage of the study during the informed consent process and throughout their participation.

To ensure a diverse representation of experiences, participants were recruited through the MSWDO and MHO of San Agustin, Surigao del Sur. These agencies assisted in identifying participants who met the criteria and invited them to participate in the study. The recruitment process was designed to capture a wide range of experiences, including those from mothers with varying educational levels, relationship statuses, and experiences of support. By using purposive sampling, the study aims to gather a broad understanding of adolescent mothers lived experiences, including challenges and coping strategies, while ensuring that the sample reflects the diversity of this population. Additionally, the MSWDO and MHO were asked to assist in reaching out to adolescent mothers from both urban and rural areas within San Agustin to further ensure a representative sample.

Research Locale

The research was conducted in San Agustin, Surigao del Sur, focusing on adolescent mothers who are currently receiving services from the Municipal Social Welfare and Development Office (MSWDO) and the Municipal Health Office (MHO). The participants include 12 adolescent mothers, with a composition of 6 single mothers and 6 mothers living with partners. The study used various data collection methods, including Focus Group Discussions (FGD)

with 12 participants, In-Depth Interviews (IDI) with 6 participants (3 single mothers and 3 mothers living with partners), and Key Informant Interviews (KII) with 3 individuals, including MSWDO staff and health personnel. Interviews were conducted in the vernacular (local dialect) to ensure comfort and clarity for the participants, but the data was translated into English for analysis and reporting.

The sample size of 12 adolescent mothers was selected based on a purposive sampling approach to gain in-depth insights into the experiences and perspectives of this specific group. This size is considered appropriate for qualitative research, particularly within a phenomenological framework, where the goal is not to generalize findings but to explore the lived experiences of participants. Focus Group Discussions (FGD) with 12 participants will provide a rich, collective understanding of the shared experiences of adolescent mothers, while the In-Depth Interviews (IDI) will allow for a more individualized exploration of the personal stories of 6 participants. The inclusion of Key Informant Interviews (KII) with 3 key individuals, such as MSWDO staff and health personnel, will provide additional contextual insights and a broader understanding of the support systems available to adolescent mothers in the community. The combination of these methods and the chosen sample size was intended to provide a comprehensive and diverse perspective on the challenges faced by adolescent mothers and their support networks.

Research Instrument

The research instrument for this study consists of a researcher-made guide questionnaire with open-ended questions designed to gather comprehensive data on the lived experiences of adolescent mothers in San Agustin, Surigao del Sur. The questionnaire was structured into sections that address the study's key objectives, which include child-rearing practices through which mothers

fulfill their children's emotional and physical requirements, their available support systems from their family members and community networks and their future ambitions which specifically include their educational objectives and life plans. In addition to the questionnaire, in-depth interviews and focus group discussions were conducted to provide participants with the opportunity to express their experiences in detail and engage in discussions that allow for a deeper understanding of their perspectives. The combination of instruments will guarantee that all study objectives require both complete examination and connection between study elements which will produce an overall understanding of adolescent mothers' difficulties and their future ambitions.

Ethical Considerations

Transparency and Conflict of Interest. To ensure transparency in the research process, the Principal Investigator (PI) and research team have disclosed any potential conflicts of interest. These include fiscal interests, familial connections, or proprietary considerations related to the study. In the case of potential conflicts, the researchers took steps to mitigate any undue influence on the study's results. A statement of no conflict of interest was included in the study's final report, and any actual or perceived conflicts were disclosed to the Research Ethics Committee (REC).

Privacy, Confidentiality, and Data Protection Plan. Privacy and confidentiality are fundamental in this study, particularly as it involves adolescent mothers. All personal data will be managed with utmost care, in compliance with the Data Privacy Act of 2012. The interview recordings were encrypted and securely stored in password-protected files, accessible only to the research team. Transcripts were anonymized, and personal identifiers were removed before analysis. Physical copies of consent forms and other personal data are stored in a locked cabinet.

Data disposal will follow the Data Privacy Act and institutional guidelines, with transcripts and recordings being securely deleted after the study's conclusion and approval by the panel. All research assistants, transcribers, and translators involved were provided with specific instructions on how to safeguard privacy and confidentiality.

A comprehensive data management plan was developed, detailing encryption protocols, access control measures, and disposal procedures for the data. This plan ensures compliance with ethical and legal standards to protect participant information throughout the research process.

Informed Consent Process. The informed consent process was conducted with the utmost respect for the autonomy of participants, especially considering the involvement of adolescent mothers. The PI clearly explained the nature of the study, its purpose, the participant's role, and any potential risks or benefits. Since adolescent mothers under 18 are considered minors, parental consent was obtained in addition to the adolescent's assent. The PI will ensure that the parents/guardians are fully informed about the study, its procedures, and their rights, and confirmed their understanding before they sign the consent form. For adolescent under 15 years old, a simplified assent form was used, and a co-signed consent form will be required for participants aged 15 to 18.

Waiver of Informed Consent. A waiver of informed consent was applied in this study, as participants are a vulnerable population. Informed consent was obtained from both the participant and, when applicable, their guardian. No data was collected without the participant's explicit consent, except in cases where it was deemed necessary for the study's integrity.

Justification for the Involvement of Vulnerable Groups. Adolescent mothers are considered a vulnerable group due to their age and the potential challenges they face in their roles as mothers. The study aims to better understand the

unique experiences of this group and provide insights that can inform support services. Specific protections were implemented, such as ensuring that interviews were conducted privately, providing appropriate support during interviews, and emphasizing confidentiality throughout the process.

Justification for Involving Minors (Under 18 Years Old). Adolescent mothers under 18 were included in the study to understand their unique experiences and challenges. This group faces distinct socio-cultural and economic issues, and their voices are essential in improving the support systems available to them. Additional safeguards were put in place, including parental consent and participant assent, as well as ensuring that the interview environment was comfortable and non-threatening.

Assent. For adolescent participants aged 12–15, verbal assent was obtained before conducting interviews. For participants aged 15–18, a simplified assent form was provided along with a co-signed informed consent form. The PI ensured that assent was obtained in a way that was understandable and appropriate for the participant's age and maturity.

Consent for Continued Participation. The consent for continued participation was not applied to all 12 participants because the age of those who participated had not yet reached the legal age.

Recruitment. The recruitment process was conducted with care to ensure that participation was voluntary and that no participant was coerced into participating. Adolescent mothers were approached through the MSWDO and MHO, where they are already receiving services. Information about the study was provided in an accessible and age-appropriate manner, and potential participants have the opportunity to ask questions before agreeing to participate.

Risks. Potential risks for participants include emotional discomfort when discussing personal challenges related to motherhood and support systems. To mitigate these risks, the interviews were conducted in a safe, confidential environment. Participants were informed that they can stop the interview at any time if they feel uncomfortable.

Benefits. Participants may benefit from the study by gaining a platform to share their experiences and challenges as adolescent mothers. Indirect benefits may include raising awareness of their needs within the community and informing them about the development of support programs. The study may also contribute to the improvement of services for adolescent mothers in San Agustin.

Safety Monitoring Plan. The safety of participants was closely monitored throughout the study. The researcher regularly asked about the emotional well-being of participants during interviews and ensured that they were comfortable. A safety monitoring plan was established to respond to any unforeseen risks.

Community Considerations. The research was conducted with sensitivity to the local community in San Agustin, Surigao del Sur. The findings will be shared with local stakeholders, including community leaders and social workers, to ensure that the results benefit the community and contribute to better support for adolescent mothers. Cultural norms and values will be respected throug hout the study.

Dissemination/Data Sharing Plan. The study's findings will be shared with the participants, stakeholders, and the broader scientific community through accessible formats such as reports and presentations. Participants will receive a summary of the results, and the findings will be published in journals or

presented at conferences to inform policy and practice regarding adolescent motherhood.

Data Gathering Instrument and Procedure

Data collection process in the current study was a mixture of both Focus Group Discussions (FGD) and In-Depth Interviews (IDI) to ensure that elaborate information was obtained about 12 adolescent mothers. The criteria used in selecting the participants were females who are between the ages of 13 to 19 years and at least had a six months mothering period. Such participants were chosen as a sample consisting of both single and living-in adolescent mothers who receive current services of the Municipal Social Welfare and Development Office (MSWDO) and the Municipal Health Office (MHO) of San Agustin, Surigao del Sur. Three Key Informant Interviews (KII) with the local health personnel and MSWDO staff were also conducted in order to get a more generalized picture of support systems that adolescent mothers have.

Ahead of starting the data collection, the researcher had forwarded a letter of request to the MSWDO in San Agustin, Surigao del Sur, to allow her to collect data on the research. After the approval was received, the process of data collection began, the IDIs and the FGDs were employed as the main data collection tools. These interviews were carried out in a secure and comfortable environment to show that the participants feel at ease and can talk about their experiences freely. The interviews were recorded on audio and transcribed word-for-word, which were analyzed later in the study with the consent of the participants.

All recordings and transcriptions were stored in files that had a password and were only accessible by the research team to ensure confidentiality and protection of personal information. All physical information, including consent forms were kept at a locked cabinet to eliminate unauthorized access.

Transcriptions were de-identified so that the anonymity of the participants during data analysis and reporting could be provided. The data security was followed with great dedication in line with the institutional and ethical principles.

Both FGDs and IDIs have interview guides that were well-formulated to encourage the subjective experiences of the participants as mothers of adolescents. Their experiences with parenthood, their struggles with it, the sources of support, and how their caregiving abilities evolved after some time were the topics. The methodology was designed to get rich and detailed accounts that would provide meaningful information about the lives of adolescent mothers in the province of San Agustin, Surigao del Sur and how they relate to the services provided by local governments.

Concerning the qualifications of the Principal Investigator (PI), the researcher met the required qualifications of conducting qualitative research and experience in handling studies involving vulnerable populations. The research submission contained the qualifications of the PI and pertinent certifications, which would ensure the integrity and ethics of the study.

The approximate time spent by each of the types of participants was presented as follows: the participants of the FGDs attended to 60-90 minutes, whereas the IDIs in the same process spent 60-120 minutes, depending on the depth of answers. The informed consent process was properly detailed to make the subjects well aware of their engagements by informing them of the total time they will be involved.

The study was done in a place that guaranteed privacy and comfort of every participant. The interviews was conducted in a secluded room at the barangay hall, MSWDO and MHO, where there were no distractions and confidentiality would not be in jeopardy.

Lastly, to guarantee that all the ethical considerations were made, USPFREC FORM 2E and 2F, as it relate to the sufficiency of facilities and the implementation of the research ethics guidelines, it was reviewed and presented with the study proposal so that the same can be approved. This action served to ensure that the study is compliant with all the institutional and regulatory expectations.

Data Analysis

Thematic analysis method was used in analyzing qualitative data collected carefully in line with the procedures described by Braun and Clarke (2006). It started by copying the recording of the interviews verbatim to obtain a precise and descriptive account of interviews. The researcher transcribed the data, after which she read and re-read the transcripts and notes to have a detailed insight into the content to ensure that she is familiar with the data. At this stage, preliminary codes were created in order to point at meaningful statements and patterns arising out of the responses.

After coding data, the second phase was to organize the coded data into themes and sub-themes, and use the research questions to interpret the findings. The themes were developed through common ideas and views on the lived experiences of the adolescent mothers including the difficulties of raising the children, support system, and future hopes. The researcher investigated the implication of these findings with regards to the lives of the participants as well as the reality of adolescent motherhood.

The researcher used various strategies to make sure that the process of analysis is rigorous. To begin with, the method of member checking was employed, and the participants were enabled to check the themes and interpretations to ascertain the validity and genuineness of the results.

Moreover, peer debriefing was performed with a professional qualified in qualitative research so as to dispute the findings and interpretations as a way to avoid bias. In addition, the researcher maintained an audit trail that contained the process of data collection, analysis, and decision-making in order to make the research process more transparent and guarantee the credibility of findings.

Lastly, the researcher took into account the contextual elements affecting the experiences of the participants to the extent that the analysis is based on the actual experiences of the adolescent mothers. Data collection was done between the months of April and August 2025 (lasting a period of five months) and then the analysis phase followed within the months of (you provide), with several validations being done with key informants particularly those data which require further clarifications to guarantee integrity and validity of data. The study timeline is a Gantt chart that is represented in Appendix B.
